

Redox rxns

Reduction-Oxidation rxns : e^- transfer.

Oxidation : when something loses e^- s

Reduction : " ————— " gains e^- s .

OIL - RIG

LEO - goes - GER

Ox is loss, red is gain (e^- s)
loss of e^- s is oxidation.
gain of e^- s is reduction.

If M loses e^- s (oxidized)

its charge becomes more +ve,
charge \uparrow

if N gains e^- s (red)

its charge becomes more -ve
charge \downarrow

We'll talk about hypothetical charges...

OXIDATION STATES/NUMBERS (OX#)

How do we assign ox#?

- we assign to each individual atom

RULES

1) Elements = ϕ ⁽⁰⁾ Na, ⁽⁰⁾ O₂, ⁽⁰⁾ P₄

2) Monatomic ion = 'charge' ⁽⁺¹⁾ Na⁺, ⁽⁻²⁾ O²⁻, ⁽⁻³⁾ P³⁻

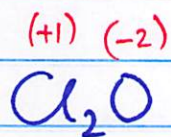

charge: # ± , ox #: ± #

3) Oxygen in cpds: -2 ⁽⁻²⁾ H₂O ⁽⁻²⁾ CO₂ ^(?) O₂F
(unless F is present)

4) Hydrogen in cpds: +1 ⁽⁺¹⁾ H₂O, ⁽⁺¹⁾ CH₄, ⁽⁻¹⁾ CaH₂
(unless metal hydride: -1)

5) Fluorine is always -1 in cpds ⁽⁺²⁾ Ca²⁺ ⁽⁻¹⁾ H⁻
other halogens in cpds are -1 ⁽⁻¹⁾ H⁻
but... if there are two diff. halogens - the highest one in gp ⁽⁻¹⁾ HF, ⁽⁻¹⁾ HCl
is -1. If O is also ^{(-1) ?} AlBr ^(?) (-2) Al₂O
present, ... (?)

6) Sum of every atom's ox # = charge

(sodium nitrite

... break into ions 1st!)

reality: $\text{Fe}^{3+} \text{Fe}^{3+} \text{Fe}^{2+}$
